Problem D. Data Structure

Input file:	standard input
Output file:	standard output
Time limit:	1 second
Memory limit:	512 mebibytes

In compute science, a stack s is a data structure maintaining a list of elements with two operations:

- 1. s.push(e) appends an element e to the right end of the list,
- 2. s.pop() removes the rightmost element in the list and returns the removed element.

For convenience, Bobo denotes the number of elements in the stack s by $\mathtt{size}(s)$, and the rightmost element by $\mathtt{right}(s)$.

Bobo has m stacks s_1, \ldots, s_m . Initially, the stack s_i contains k_i elements $a_{i,1}, \ldots, a_{i,k_i}$ where $a_{i,j} \in \{1, \ldots, n\}$. Furthermore, for each $e \in \{1, \ldots, n\}$, the element e occurs in the m stacks **exactly twice**. Thus, $k_1 + \cdots + k_m = 2n$.

A sorting plan of length l consists of l pairs $(f_1, t_1), \ldots, (f_l, t_l)$. To execute a sorting plan, for each $i \in \{1, \ldots, l\}$ in the increasing order, Bobo performs s_{t_i} .push $(s_{f_i}$.pop()).

A sorting plan is *valid* if the length does not exceed $\lfloor \frac{3n}{2} \rfloor$, and for each $i \in \{1, \ldots, l\}$, $1 \leq f_i, t_i \leq m$, $f_i \neq t_i$. Before the *i*-th operation,

- size $(s_{f_i}) > 0$,
- size $(s_{t_i}) < 2$,
- either $\operatorname{size}(s_{t_i}) = 0$ or $\operatorname{right}(s_{f_i}) = \operatorname{right}(s_{t_i})$.

Also, after the execution of a valid sorting plan, each of the m stacks either is empty or contains the two copies of the same element.

Find a valid sorting plan, given the initial configuration of the m stacks.

Input

The input consists of several test cases terminated by end-of-file. For each test case,

The first line contains two integers n and m.

For the next m lines, the *i*-th line contains an integer k_i , and k_i integers $a_{i,1}, \ldots, a_{i,k_i}$.

- $1 \le n \le m \le 2 \times 10^5$
- $0 \le k_i \le 2$ for each $1 \le i \le m$
- $1 \le a_{i,j} \le n$ for each $1 \le i \le m, 1 \le j \le k_i$
- For each $1 \le e \le n$, there exists exactly two (i, j) where $1 \le j \le k_i$ and $a_{i,j} = e$.
- In each input, the sum of m does not exceed 2×10^5 .

Output

For each test case, if there exists a valid sorting plan, output an integer l, which denotes the length of the sorting plan. Followed by l lines, the *i*-th line contains two integers f_i and t_i . Otherwise, output '-1'. If there are multiple valid sorting plans, any of them is considered correct.

Examples

standard input	standard output
2 3	3
2 1 2	1 3
2 1 2	2 3
0	2 1
1 1	0
2 1 1	-1
3 4	
2 1 3	
2 2 3	
1 1	
1 2	

Note

For the first test cases,

- Initially, $s_1 = [1, 2], s_2 = [1, 2], s_3 = [].$
- After $s_3.push(s_1.pop())$. $s_1 = [1], s_2 = [1, 2], s_3 = [2]$.
- After $s_3.push(s_2.pop())$, $s_1 = [1]$, $s_2 = [1]$, $s_3 = [2, 2]$.
- After $s_1.push(s_2.pop())$, $s_1 = [1, 1]$, $s_2 = []$, $s_3 = [2, 2]$.

For the second test case, the initial configuration is already sorted.
