## Problem D. Differencia

| Input file: | standard input |
| :--- | :--- |
| Output file: | standard output |
| Time limit: | 30 seconds |
| Memory limit: | 256 mebibytes |

Professor Zhang has two sequences $a_{1}, a_{2}, \ldots, a_{n}$ and $b_{1}, b_{2}, \ldots, b_{n}$. He wants to perform two kinds of operations on the sequences:

-     + $l r x$ : set $a_{i}$ to $x$ for all $l \leq i \leq r$.
- ? $l r$ : find the number of $i$ such that $a_{i} \geq b_{i}$ and $l \leq i \leq r$.

## Input

There are multiple test cases. The first line of input contains an integer $T$ indicating the number of test cases. For each test case:
The first line contains four integers $n, m, A$ and $B\left(1 \leq n \leq 10^{5}, 1 \leq m \leq 3000000,1 \leq A, B \leq 2^{16}\right)$ : the length of the sequence, the number of operations and two parameters. The second line contains $n$ integers $a_{1}, a_{2}, \ldots, a_{n}\left(1 \leq a_{i} \leq 10^{9}\right)$. The third line contains $n$ integers $b_{1}, b_{2}, \ldots, b_{n}\left(1 \leq b_{i} \leq 10^{9}\right)$.
As the number of operations can be rather large, the $m$ operations are specified by parameters $A$ and $B$ given to the following generator routine.

```
int \(\mathrm{a}=\mathrm{A}, \mathrm{b}=\mathrm{B}, \mathrm{C}={ }^{\sim}(1 \ll 31), \mathrm{M}=(1 \ll 16)-1\);
int rnd (int last) \{
    \(\mathrm{a}=(36969+(\) last \(\gg 3)) *(\mathrm{a} \& \mathrm{M})+(\mathrm{a} \gg 16)\);
    \(\mathrm{b}=(18000+(\) last \(\gg 3)) *(\mathrm{~b} \& \mathrm{M})+(\mathrm{b} \gg 16)\);
    return (C \& (( \(\mathrm{a} \ll 16)+\mathrm{b})) \% 1000000000\);
\}
```

For the $i$-th operation, first call $\operatorname{rnd}($ last $)$ three times to get $l, r$ and $x($ that is, $l=\operatorname{rnd}($ last $) \bmod n+1$, $r=\operatorname{rnd}($ last $) \bmod n+1, x=\operatorname{rnd}($ last $)+1)$. Then, if $l>r$, you should swap their values. And at last, the $i$-th operation has type '?' if $(l+r+x)$ is an even number, or type ' + ' otherwise.
Note: last is the answer of the latest type '?' operation. Assume last $=0$ at the beginning of each test case.
There are at most 300 test cases, and the total size of the input is at most 8 mebibytes.

## Output

For each test case, output the integer $S=\left(\sum_{i=1}^{m} i \cdot z_{i}\right) \bmod \left(10^{9}+7\right)$, where $z_{i}$ is the answer for $i$-th query. If the $i$-th query is of type ' + ', assume $z_{i}=0$.

## Example

| standard input |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 3 |  |  | 81 | standard output |  |
| 5 | 10 | 1 | 2 |  | 88 |
| 5 | 4 | 3 | 2 | 1 |  |
| 1 | 2 | 3 | 4 | 5 |  |
| 5 | 10 | 3 | 4 |  | 87 |
| 5 | 4 | 4 | 2 | 1 |  |
| 1 | 2 | 3 | 4 | 5 |  |
| 5 | 10 | 5 | 6 |  |  |
| 5 | 4 | 5 | 2 | 1 |  |
| 1 | 2 | 2 | 4 | 5 |  |
