

Distinct Parity Excess

Problem ID: distinctparityexcess

Time limit: 3 seconds

A property of any positive integer is its *prime parity*, which is derived from the count of its distinct prime factors. If this count is even, the prime parity is even; if the count is odd, the prime parity is odd.

You are given a sequence of ranges to test. Each range is given as two numbers a and b , defining the range from a to b inclusive. You want to compute the excess of even parity integers over odd parity integers over this range. If there are more odd parity integers, the computed difference will be negative.

Input

The first line of the input contains a single integer n ($1 \leq n \leq 100$), which is the number of ranges to test.

Each of the next n lines contains two integers a and b ($2 \leq a \leq b \leq 10^7$), which is a range to test.

Output

Output n lines, one for each range in the input. For each range, output a single integer giving the excess of even parity integers over odd parity integers.

Sample Input 1

```
3
2 2
2 5
2 10
```

Sample Output 1

```
-1
-4
-5
```

Sample Input 2

```
8
2 100
2 50
50 100
2 1000
100 143
2 1000000
80000 90000
1000000 1000000
```

Sample Output 2

```
13
-1
15
63
0
-1909
-31
1
```
